

Produce Facts

STABY

# Mandarin/Tangerine

## Recommendations for Maintaining Postharvest Quality

Mary Lu Arpaia<sup>1</sup> and Adel A. Kader<sup>2</sup>

<sup>1</sup>Department of Botany and Plant Sciences, University of California, Riverside, CA 92521

<sup>2</sup>Department of Pomology, University of California, Davis, CA 95616

**Maturity Indices**      Color (yellow, orange, and/or red) on 75% of fruit surface and soluble solids/acid ratio of 6.5 or higher.

**Quality Indices**      Color intensity and uniformity; size; shape; firmness; freedom from decay; and freedom from defects including freezing injury, chilling injury, insect damage, and scars. Flavor depends upon soluble solids/acid ratio and absence of off-flavors.

**Optimum Temperature**      5-8°C (41-46°F) for 2 to 6 weeks, depending on cultivar, maturity-ripeness stage at harvest, and decay control treatments used.

**Optimum Relative Humidity**      90-95%

Rates of Respiration	Temperature	5°C (41°F)	10°C (50°F)	15°C (59°F)	20°C (68°F)
	ml CO <sub>2</sub> /kg·hr	2-4	3-5	6-10	10-15

• To calculate heat production multiply ml CO<sub>2</sub>/kg·hr by 440 to get Btu/ton/day or by 122 to get kcal/metric ton/day.

**Rates of Ethylene Production**      < 0.1 µl/kg·hr at 20°C (68°F)

**Responses to Ethylene**

- Mandarins and tangerines can be degreened by exposure to 1-10 ppm ethylene for 1-3 days at 20 to 25°C (68 to 77°F)
- Removal of ethylene from transport vehicles and storage facilities for citrus fruits can help reduce decay incidence.

<b>Responses to Controlled Atmospheres (CA)</b>	A combination of 5-10% O <sub>2</sub> and 0-5% CO <sub>2</sub> can delay color changes from green to yellow and other symptoms of senescence, but it is not very effective in decay control. Mandarins do not tolerate exposure to fungistatic CO <sub>2</sub> levels (10-15%). Commercial use of CA is very limited.
<hr/>	
<b>Physiological Disorders</b>	<b>Chilling injury:</b> Symptoms include pitting and brown discoloration followed by increased susceptibility to decay. Severity increases with longer exposures to lower temperature below 5°C (41° F).  <b>Oil spotting (Oleocellosis):</b> Harvesting and handling turgid citrus fruits can result in breaking of oil cells and release of oil that damages surrounding tissues.  <b>Aging:</b> Symptoms include shriveling and peel injury around the stem end.
<hr/>	
<b>Pathological Disorders</b>	<b>Major Diseases:</b> <ul style="list-style-type: none"><li>• Green mold (<i>Penicillium digitatum</i>)</li><li>• Blue mold (<i>Penicillium italicum</i>)</li><li>• Phomopsis stem-end rot (<i>Phomopsis citri</i>)</li><li>• Stem end rot (<i>Lasiodiplodia theobromae</i>)</li><li>• Brown rot (<i>Phytophthora citrophthora</i>)</li><li>• Anthracnose (<i>Colletotrichum gloeosporioides</i>)</li></ul> <b>Control Strategies:</b> <p>Reduce the pathogen population in the environment</p> <ol style="list-style-type: none"><li>1. Effective preharvest disease control.</li><li>2. Use of chlorine in wash water.</li><li>3. Heat treatments.</li><li>4. Effective sanitation procedures</li></ol> <p>Maintain fruit resistance to infection</p> <ol style="list-style-type: none"><li>1. Minimize mechanical injuries.</li><li>2. Use proper ranges of temperatures and relative humidity throughout postharvest handling.</li><li>3. Use postharvest fungicides and/or biological antagonists.</li><li>4. Avoid exposure to ethylene.</li></ol>
