Greenhouse forcing of hydrangeas is not an easy task. However, a successful crop can be grown if a few key steps are followed. Listed below are some main points to keep in mind if you plan to grow hydrangeas.

Receiving and Establishing Pre-Cooled Plants

Hydrangeas are usually shipped in the late fall through early winter, after they have received a required cold storage treatment. They are received as dormant plants in 4-6" pots or as bare-root plants previously grown in 4" pots. Newly received plants should be allowed to initiate active root growth (for about 5 to 7 days) prior to transplanting into the final-sized pot. The ideal starting temperature for hydrangeas is a 60-62 °F soil temperature supplied with bottom heat, while maintaining slightly cooler air temperatures (58 °F). This allows root activity prior to buds opening on the shoots. Grow plants slightly on the "dry side" prior to transplant to prevent root rot and to encourage root development. No fertilizer should be applied until root activity and transplanting have occurred.

One of the main problems encountered with hydrangeas is poor root establishment leading to water stress damage during late stages of forcing. At transplant, the bottom of the root ball should be slit twice (to form an X pattern), about of the way up towards the top to form four sections; split open these sections and place them in direct contact with the soil in the new pot.

Flower Color Control

The key in assuring clear pink or blue inflorescences is ordering plant material programmed to develop the desired color and continuing the color program throughout forcing. Fertilization practices during the previous summer growth phase can affect coloration during forcing, and changing the color program during the forcing phase can result in interesting shades of mauve sometimes referred to as "blurple" tones.

Whether a hydrangea (excluding white cultivars) develops a pink or blue inflorescence is dependent on the presence and availability of aluminum. The absence of aluminum assures pink flowers; high availability of aluminum leads to blue flowers. By regulating aluminum, flower color can be controlled.

Cultivars vary in color tones and some are better suited for pinks while others are best produced as a blue. Select the cultivar with the color and tone best suited for your market demands. Although there are over 500 cultivars of hydrangeas, only a few are produced to any large degree (Table 1).
The cultivars recommended for a dark pink to red are ‘Böttstein’ and ‘Schenkenburg’; medium pinks include ‘Merritt’s Supreme’, ‘Kasteln’, and ‘Red Star’; and ‘Rose Supreme’ and ‘Enziandom’ produce light pink flowers. Some cultivars such as ‘Mathilde Gütges’ and ‘Brüstenburg’ do not produce a consistent or clear pink and should be programmed as blue flowers only.

Blue Flowers. Although dormant plants purchased as blues will have received aluminum sulfate prior to shipment, aluminum must also be supplied during the forcing period. Start drenching with aluminum sulfate immediately after transplant. Apply 8 fl oz of drench per 6" pot using 10 lb aluminum sulfate/100 gallons of water. Drenches should be made to moist substrate only; drenching dry soil will result in damaged roots. Make applications at 10-14 day intervals. About 10 days after each application, measure the pH of the substrate. If the pH is higher than 5.6, another application of aluminum sulfate should be made. Continue this procedure throughout forcing. The aluminum sulfate not only supplies aluminum, it also maintains a low (5.2-5.5) pH in the substrate solution, desirable during forcing of blue hydrangeas. If the pH of the irrigation water is higher than 5.8, consider acidifying to 5.3. A 35% sulfuric acid source (should be available at auto supply stores) is the best acidifier for blue hydrangeas, as it will not add unwanted phosphorus and is not as caustic as a more concentrated acid.

Use a phosphorus-free substrate for transplanting and use a fertilizer lacking phosphorus. Apply high levels of potassium for increased bluing. For example, apply 150 ppm nitrogen and 300 ppm potassium at each irrigation supplied with ammonium nitrate (2oz/100 gal) plus potassium nitrate (11 oz/100 gal).

Height Control
Most hydrangeas, especially tall growing cultivars (Table 2), require height control during forcing. Apply B-Nine® sprays using 2500 ppm (most cultivars) to 5000 ppm (tall cultivars, especially ‘Rose Supreme’). First applications are made when 3-5 leaf pairs have begun to unfold, about 3-4 weeks after the start of forcing. Under poor light conditions, repeat applications may be necessary at 10-14 day intervals. Treatments should be discontinued prior to when flower buds reach ¼" in diameter or inflorescences will be reduced in size at maturity. The following PGR treatments have been reported effective on hydrangeas, although they are not labeled: A-Rest® foliar sprays (50-100 ppm), A-Rest® substrate drenches (2-4 mg a.i./pot), Bonzi® sprays (50-100 ppm) Cycocel® drenches (0.3-1.6 g a.i./pot), and Sumagic® sprays (5-15 ppm).

Temperature and Timing
The rate of hydrangea development during forcing is directly related to average daily temperature, and to a certain degree, forcing speed can be regulated by adjusting temperature (Table 3). Generally, plants are forced in 80-100 days using 60°F nights/70°F cloudy day/75°F sunny day temperatures until flowers begin to show color (about 2½ weeks to sales date) then dropping the temperature until full coloration. At start of color, the temperature should be dropped to 54°F night/65°F day to intensify flower color.

Hardening and Post-Production Handling
At start of visible flower color, fertilization should be cut in half to help harden plants. Fully colored flowers are tender, and some shading to prevent overheating is beneficial during the last few weeks of production, especially for late crops such as for Mother’s Day. Watering should be slowly reduced, but under no circumstances should plants be allowed to wilt.

Hydrangeas exhibit a long post-harvest life in the home if kept moist, out of direct light, and relatively cool. The key word for retailers and home owners is Water. Hydrangeas are very unforgiving when it comes to wilting and will never fully recover if allowed to dry out.

Pests and Diseases
Greenhouse pests and diseases differ from location to location. Listed below are the major problems of hydrangeas. Problems most likely to be encountered are indicated by the “helping hands”:

The Future For Hydrangeas

Forcing of hydrangeas for Valentine’s Day is already common for many producers, and the trend seems to be increasing. The sales period for hydrangeas is definitely increasing and will continue to expand.

There is an increase in small (4½"-5" pots), single-stem hydrangeas. It should be possible to grow them and flower plants in a year-round program.

Another change which may take place in the future is an increase in the cultivars of the florists’ hydrangea (*Hydrangea macrophylla subsp. macrophylla var. macrophylla*) and hydrangea species being produced. An example of “new” cultivars would be ‘Kasten’. A few years ago, it was relatively unknown; now it is becoming a major cultivar for late-season forcing.

With regards to new species, look for ‘Pia’ (*Hydrangea x ‘Pia’*) in the next few years. This selection is very dwarf, faster forcing than current cultivars, and very winter hardy. Pia is also noted because it appears to be a “non-bluing” cultivar that blooms pink regardless of how it is treated.

Other possible new hydrangeas include the lacecap varieties (*Hydrangea macrophylla subsp. macrophylla var. normalis*) such as ‘Lybella’, ‘Blue Sky’, ‘Taube’, ‘Sunset’, ‘Shower’, and ‘Tricolor’, which has variegated foliage. The lacecaps have a more open inflorescence and force more quickly than the florists’ hydrangeas, you should consider experimenting with a few lacecaps this season.
